CPSC 103 - Systematic Program Design

Module 01 Day 2

Ian Mitchell, with thanks to Rik Blok & Giulia Toti

Reminders

- Mon: Module 2: Pre-Lecture Assignment
- Mon: Syllabus Quiz
- Mon: Module 1 (Intro): Worksheet
- Wed-Fri: Module 2 Tutorial Attendance
- Wed: Module 1 (Intro): Code Review
- Wed: Module 1 (Intro): Tutorial Submission

See your Canvas calendar (https://canvas.ubc.ca/calendar) for details.

Module 1: Learning Goals

At the end of this module, you will be able to:

- Write statements that operate on primitive data including numbers, strings and booleans.
- Write variable definitions and function definitions.
- Write out the step-by-step evaluation of simple statements including function calls.
- Use Jupyter notebooks to run Python code.

C

iClicker check-in

How are you doing? Any trouble keeping up?

- A. 💪 Easy-peasy... you can go faster
- B. 👍 Yup, I got this
- C. D I might have missed a bit here or there
- D. (2) Hmm, something's not working right
- E. I have no idea what's going on

Exercise 1

Try these for yourself in the code cell below:

- put 10 in variable a
- put 66 in variable y
- copy value stored in y to x
- evaluate x > y

In []:

► i Sample solution (For later. Don't peek if you want to learn ①)

Exercise 2

- put "y" in variable x
- test if y is equal to x

Note that y exists because we ran the cell above. Check what happens if you restart the notebook and run this cell first.

In []:

► I Sample solution (For later. Don't peek if you want to learn ⊕)

Exercise 3

- 1. Put your name in a variable name .
- 2. Test if name is greater than "Rik".

Questions

- 1. What happens if you forget the quotes around your name? Why?
- 2. What does it mean for one string to be greater than another?
- 3. Is your name greater than "Rik"? Why or why not?

For the values associated to each character, you can look up an ASCII table.

In []:

► ii Sample solution (For later. Don't peek if you want to learn 🙂)

iClicker check-in

How are you doing? Any trouble keeping up?

- A. 6 Easy-peasy... you can go faster
- B. 👍 Yup, I got this
- C. 😕 I might have missed a bit here or there
- E. 🔞 I have no idea what's going on

iClicker question

We'll use functions next. Before we dive in, though, what is a *function* in Python?

- A. A collection of related data
- B. A loop that repeats a set of instructions
- C. A conditional statement that runs depending on certain conditions
- D. A variable that stores a value
- E. A set of instuctions that performs a specific task
 - ► ii Hint (for your review after class)

Date facts

Let's check some fun facts that happened on a date. We will use the the API http://numbersapi.com/. Think of an API a way for us to communicate with another computer to get the information we need.

First, we have to import the date_fact library, that contains the code to use the API:

In []: # This indicates we are going to use some code from the date_fact.py file
from date_fact import *

i File extensions .py vs .ipynb

If you look into your Syzygy directory, you will notice the files date_fact.py and module01-day2.ipynb (the latter is this file that we are looking at).

The extension .ipynb means that the file is a Jupyter notebook. Notebooks have cells which can be formatted in fancy ways (such as code or markdown) and executed in Jupyter (press [Shift]-[Enter] or the [Run] toolbar button). These are the files that you will be using for most work in the course.

The extension .py means that the file contains only Python code. You can still open the file in Syzygy to read, edit or add to the code, but you cannot create cells or run the code directly. Instead, you will typically import these files into your Jupyter notebooks; for example, as we did in the cell above for date fact.py.

Function signatures

To use any supplied function we need to know its signature, or its...

- name,
- arguments, and
- return value.

The code inside the file date_fact.py gives us the following functions:

```
get_date_fact(month: int, day: int) -> strget_number_fact(number: int) -> str
```

• get_year_fact(year: int) -> str

```
In [ ]: # Get some trivia from the year you were born!

# First, take a Look at the names of the functions. Out of the three
# functions listed above, which one do you think we should use?

# Now, Look at the signature of the function you have chosen.
# What kind of information does it ask for (hint: what parameters are listed
# in the signature)?

# Try to call (i.e., use) the function!
get_year_fact(2000)
```

Include the year

Notice how the output from the function does not include the year. The argument does not necessarily need to be included in the output of a function.

Without changing the function itself, let's change the cell's output to display a sentence that also states the year, like

In 2000, ...

```
In [ ]: "In 1990, " + get_year_fact(1990) + "."
```

Changing things up

What happens if we want to find facts from another year?

Is there an easier way to change the value of the year without having to remember all the places the year appeared in?

Mixing data types

- Recall, we've seen a few different primitive types: int , float , and str
- Different types don't always mix:
 - **✓** 1 + 1 ⇒ 2
 - '1' + '1' ⇒ '11'
 - \bigcirc '1' + 1 \Rightarrow Syntax error
- You might find the str function useful. It converts a number into a string

```
In [ ]: year = 2000
# Rewrite your expression above so that it uses the variable `year`
```

► ii Sample solution (For later. Don't peek if you want to learn 🙂)

What happened on your date of birth?

Write some code to find an event that happened on your birth date (month and day). Follow the same steps as before.

- 1. Take a look at the names of the functions. Out of the three functions listed above, which one should we use?
- 2. Take a look at the signature. What pieces of information is the function asking for? What kinds of data types are they?
- 3. Try to call the function!

```
In [ ]:
```

► i Sample solution (For later. Don't peek if you want to learn 🙂)

Include the month and day

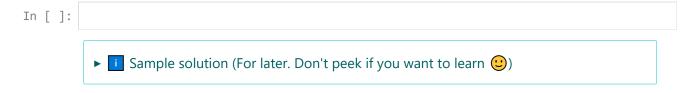

Now, try to include information about your date of birth before the fun fact in a sentence! For example, if your birthday was on *September 16* and the fact produced for this particular day is

'the Cape Verde Islands, Mozambique, and Sao Tome and Principe join the United Nations'

then your code should produce

'On 9/16 the Cape Verde Islands, Mozambique, and Sao Tome and Principe join the United Nations.'

Can you do this in a way that makes it easy for us to change the values for the birth month and day?

Improving on greatness

Let's make the output better.

Instead of using numbers to describe a month, let's use the month's abbreviated (3- or 4-letter) name. For example, instead of '9/16' let's write 'Sept 16'.

For this task we'll use the if/elif/else statement, first introduced in question 16 of the Module 1 (Intro) worksheet, due on Monday.

elif keyword

The Python keyword elif stands for "else if" – it only gets checked if none of the previous condition(s) were True.

iClicker question: if/elif

```
output = "Initial value"
Consider the program to
                         number = -23
the right. What does it
                         if number > 0:
produce when it is run?
                              output = "Bigger than zero!"
                         elif number > -10:
 A. "Initial value"
                             output = "Bigger than minus 10."
 B. "Bigger than zero!"
                         elif number > -20:
                              output = "Very small!"
 C. "Bigger than minus
                         output
    10."
 D. "Very small!"
```

► ii Hint (for your review after class)

E. Something else

```
In [ ]: # Enter your birth date (month and day)
month = 9
day = 16

# Construct a sentence that reports your birth date
# with the name of the month and a fact about that day.
```

► i Sample solution (For later. Don't peek if you want to learn ①)

How to handle invalid data?

What if the user enters an invalid number for the month (not 1..12)? How should we handle that case?

Let's go back up to the code cell above and revise our code to handle this special case.

► I Sample solution (For later. Don't peek if you want to learn (□)

Swapping variables

Let's get more familiar with how variables store data. In Computer Science we often need to swap the contents of two variables, $\, x \,$ and $\, y \,$. So, after the swap, $\, x \,$ now holds what was originally in $\, y \,$, and vice versa.

How can we do that?

iClicker question: Swapping

Let's say we begin with two variables assigned values x = 5 and y = 10. Which of the following programs will successfully swap the variables so their final values are x = 10 and y = 5? Select **ALL** that apply. [iClicker: Change poll type to Multiple Answer]

```
(A)
                                          (B)
                                          oldx = x
x = y
                                          oldy = y
y = x
                                          x = oldy
                                          y = oldx
(C)
                                          (D)
oldx = x
                                          oldx = x
x = y
                                          y = oldx
y = oldx
                                          x = y
 ► ii Hint (for your review after class)
```

iClicker check-in

How are you doing? Any trouble keeping up?

A. 💪 Easy-peasy... you can go faster

B. 👍 Yup, I got this

C. 😕 I might have missed a bit here or there

D. (2) Hmm, something's not working right

E. 💎 I have no idea what's going on

Writing your own functions

So far, we have learned that functions are pretty great!

- Code re-use: They allow us to perform an action without having to rewrite the code every time
- Abstraction: We can use other people's functions without knowing how they work, just what arguments they need and what they return

Naturally, you will want to be able to write your own functions.

Checking the sign

Problem: Check if a number is positive or negative.

Steps:

- 1. Assign a number to a new variable.
- 2. Create a blank string variable output .
- 3. Fill the output with text that indicates whether number is positive or negative.
- 4. Display the contents of output.

```
In [ ]: # Step 1. Assign a number to a new variable.

# Step 2. Create a blank string variable output.

# Step 3. Fill the output with text that indicates whether number is positive or new text.

# Step 4. Display the contents of output.
```

► I Sample solution (For later. Don't peek if you want to learn ⓐ)

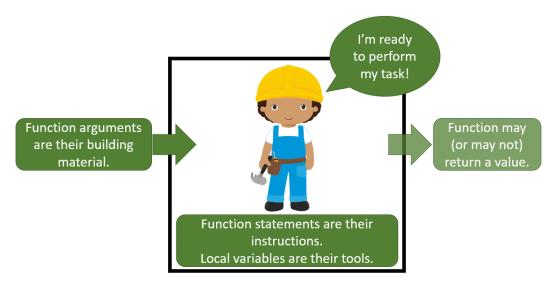

Special cases

You should always consider special cases you might need to handle.

Are there any special cases for this problem? How should we handle them? Let's implement that in our code, above.

► i Sample solution (For later. Don't peek if you want to learn 🙂)

Let's do it again, but make a function

Here is another way to think about functions

Checking the sign (refactored)

Problem: Check if a number is positive or negative.

Task:

Write a function that:

- 1. Takes a number as an argument.
- 2. Creates a local string variable output .
- 3. Fills the output with text that indicates whether number is positive or negative.
- 4. Returns the contents of output.

In []:

► i Sample solution (For later. Don't peek if you want to learn ⊕)

Things to notice

- The statements contained within the function (its body) are all indented.
- The argument type (int) and function return type (str) aren't required here. But we'll require them later so we're introducing them here.
- How could we rewrite the function so that it doesn't need the local variable output?

Now, test our function by calling it with a few different numbers (or variables).

In []:

C

iClicker question

Imagine you want to write a function to compute how many one-Litre cans of paint are needed to paint a wall. Which of the following are good arguments for this function? Select **ALL** that apply.

- A. Height of the wall
- B. Width of the wall
- C. Thickness of the wall
- D. Size of a can
- E. Number of cans needed
 - ► i Hints (for your review after class)

iClicker question

We want to write a function that repeats a given string. Which of the following are correct? Select **ALL** that apply. Try to answer this question based on your knowledge, without running the code.

iClicker question

We want to write a function that repeats a given string. Which of the following are correct? Select **ALL** that apply. Try to answer this question based on your knowledge, without running the code.

```
A. def 2_times(thing):
    return thing+thing
B. def repeat_it(string):
    string*2
C. def repeat_string_once2(string):
    return 'string' + 'string'
D. def repeat_string_once(string):
    return string*2
E. def repeat(s):
    new_s = s + s
    return new_s
```

► i Hints (for your review after class)

```
In [ ]: # Reproduce those functions here and try calling them! (Watch your indentation!)
```

iClicker check-in

How are you doing? Any trouble keeping up?

- A. 💪 Easy-peasy... you can go faster
- B. 👍 Yup, I got this
- C. D I might have missed a bit here or there
- D. Hmm, something's not working right
- E. P I have no idea what's going on

iClicker question: sqrt

Recall question 10 from the pre-class reading quiz:

x = 9

sqrt(9) # a built-in math function that returns the square root of its
input

What is the value of x after the function call? (If it helps, you can add the code to the cell below and run it.)

- A. 9
- B. 3
- C. 3.0
- D. Something else
 - ► i Hints (for your review after class)

In []: from math import *
